BRIEF DESCRIPTION
The depiction of violence is the focus of many content analyses of video games. Typically, the occurrence and nature of acts of violence or aggression are coded to quantify the amount of violent content in a particular game.

FIELD OF APPLICATION/THEORETICAL FOUNDATION
Quantifying the amount of violence in video games can inform media effects research that looks at the relationship between the exposure to violent video game content and aggression. This allows for more precise measures and hypotheses than simply coding a game as violent or nonviolent which is often done in experimental research in this area. What is commonly coded in content analyses of violent content in video games is the number and nature of aggressive or violent actions. Specific attributes of these acts, such as their realism, graphicness or (narrative) justification (Tamborini et al., 2013) are only considered in a few studies (e.g., Lachlan et al., 2005). While the focus in most studies is on acts of physical aggression/violence in interactions with/between game characters, there are also studies that have investigated verbal aggression between players (Holz Ivory et al., 2017).

REFERENCES/COMBINATION WITH OTHER METHODS OF DATA COLLECTION
Content analysis of violence in video games can be complemented by survey data asking players about the games they play and their rating of the degree of violence they contain and/or age rating from institutions like ESRB or PEGI (see Buching et al., 2015).
